# The innovating bedding system

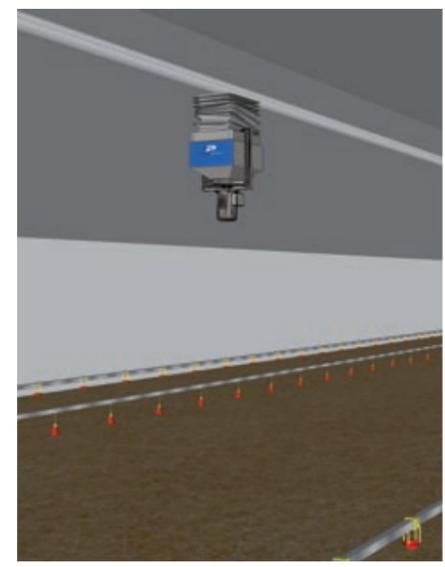

## BeddingPoint

The health of cattle, pigs and poultry depends on several factors and is critical for farmers in terms of the profitability of their farms. The bedding in the barn is a key factor. It provides insulation from the cold rising from the ground, creates a favourable microclimate, and acts as an absorbent layer for droppings and water.

The fully automatic **BeddingPoint** system developed by Prüllage virtually revolutionises the bedding process in barns. The advantages over the conventional system are enormous in several respects. There is no need for a tractor or any other machine to deliver the litter and scatter it evenly throughout the complete cycle. This also means that no staff is required and the barn doors can be kept closed. This improves hygiene standards in the barn. It also prevents the infiltration of rodents and vermin which would otherwise keep causing health problems.

The new system puts an end to high levels of noise and dust. It is also possible to spread the litter much more finely and there is no longer any need for a building to store the straw. All these advantages lower costs and reduce stress for both animals and humans.

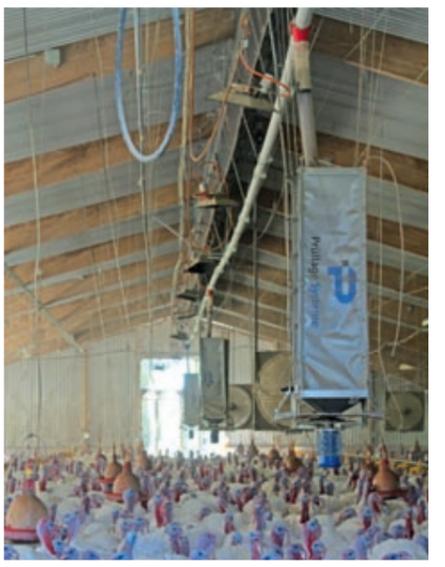

The **BeddingPoint** system is easy to use and is simply attached to the barn ceiling where it economizes on space. There are no rails needed. It is automatically filled with absorbent bedding materials from an internal or external silo through a spiral conveyor. The litter is then transported to the turntable through a flexible container with a feed hopper underneath. Depending on the age and weight of the animals, this enables an exact and even distribution which can be adjusted to the heights of the feeding and drinking lines.

Even distribution of the bedding in the barn
